Experiment 08

Use of Inbuilt functions and relational algebra operation

Aim:

To create a relational database that stores information about departments and employees, and to perform various SQL queries to analyze employee data.

Problem Statement:

The task is to manage employee and department data effectively, allowing for various analyses such as average salary calculation, employee counts, and salary comparisons across different roles and departments. The goal is to facilitate easy retrieval of information for decision-making and reporting.

Theory:

Relational databases use tables to store data in a structured format, allowing for relationships to be established between different entities (in this case, employees and departments). SQL (Structured Query Language) is used to query and manipulate the data stored in these tables. Key concepts include:

- Tables: A way to organize data into rows and columns.
- Primary Keys: A unique identifier for each record in a table.
- Foreign Keys: A field in one table that uniquely identifies a row of another table, establishing a relationship between them.
- Aggregate Functions: Functions such as `AVG()`, `SUM()`, and `COUNT()` used
 to perform calculations on a set of values.

Commands Used:

- 1. Database and Table Creation
- 2. Data Insertion

Conclusion

The SQL code successfully creates a relational database structure that allows for effective storage and retrieval of employee and department data. The queries implemented demonstrate the capability to analyze employee data, providing insights into salary distributions, employee counts, and unique hire dates. This database can serve as a foundation for more complex analyses and reporting, contributing to better management and decision-making in an organizational context.

Future enhancements could include more advanced data integrity checks, additional tables for roles or job histories, and more complex queries for deeper insights.
